Exact bounded-error continuous-time linear state estimator

Simon Rohou*, Luc Jaulin*

*ENSTA Bretagne, Lab-STICC, UMR CNRS 6285, Brest, France

Abstract

This paper proposes an interval-based method for estimating the state of a linear continuous-time dynamical system. In this work, we assume that the measurements are provided at discrete times and that all errors are bounded. Interval analysis is used to propagate the interval uncertainties continuously over time. The resulting method is guaranteed to never lose any feasible solution and provides an optimal polygonal enclosure of the state trajectory. A reproducible example illustrates the principle of the method.

Keywords: linear system, state-space equations, interval analysis, tubes, time uncertainties, state estimator.

1. Introduction

This paper proposes a new state estimator for linear time-invariant systems described by state equations. The measurements are collected at discrete times and all errors are assumed to be intervals. The states are known to belong to some prior sets, possibly infinite if nothing is known a priori. Using interval analysis, we show that it is possible to obtain an accurate and guaranteed enclosure of the state vectors that is consistent with the state equation, the observations and the related errors. This state estimator is exact since it does not introduce pessimism and does not lose any consistent state.

The state estimation of linear systems is usually treated by a Kalman filter [1, 2]. Since several decades, the Kalman approach has been adapted to consider bounded-error systems [3, 4, 5]. This set-membership approach is interesting when we have few measurements [6] or when the noise is more properly described by intervals rather than a probabilistic distribution. For the resolution, different types of wrappers have been used to enclose the feasible states: ellipsoids [7, 8], intervals [9, 10], zonotopes [11, 12, 13], paralleloptopes [14], or polytopes [15, 16]. All these contributions consider a discrete time evolution.

The approach proposed in this paper is an extension of the method introduced in [16], which is dedicated to discrete time systems. This method has been shown to be exact and can be written in a recursive form. Now, the main difficulty is to take into account the continuous time, the discrete measurements and the accuracy of the enclosure, in one algorithm.

Dealing with continuous time has already been considered by several authors such as [17]. Our main contribution is to propose a state estimator based on interval analysis that computes exactly the set of all feasible trajectories. To our knowledge, none of the existing state estimators is able to compute this exact set in the case of continuous linear systems. They either require the system to be discrete in time (see e.g., [16]) or they introduce some conservatism [18]. The overestimation of linear continuous-time state estimator is mainly due to the fact that necessary conditions [19] are used, such as positivity, see e.g. [20], or wrapping effects.

This paper is organized as follows. Section 2 introduces the exact sequence defining the set of all states consistent with the errors and the differential equation associated with the evolution. Section 3 specifies the exact sequence in the case where the system is linear and time-invariant. It also proposes a polygonal algorithm for computing an outer approximation of the exact state trajectory. Finally, an example related to the localization of a mobile robot is treated in Section 4, before the conclusion of the paper.

2. Exact sequence

2.1. Tubes

Denote by \( \mathcal{F}(\mathbb{R} \rightarrow \mathbb{R}^n) \) the set of trajectories with values in \( \mathbb{R}^n \). A tube [21] is a set of trajectories \( X(\cdot) : \mathbb{R} \rightarrow \mathcal{P}(\mathbb{R}^n) \) which satisfies

\[
X(\cdot) \in X(\cdot) \Leftrightarrow \forall t, x(t) \in X(t).
\]

This definition shows that any value \( x(t) \) is enclosed in a set. Nevertheless, there is no additional information related to temporal correlations or derivatives with respect to \( t \). For instance, the set of trajectories \( \mathcal{A}(\cdot) : t \rightarrow [-1, 1] \) is a tube, and the trajectory \( a(t) = \sin(t) \) is enclosed in \( \mathcal{A}(\cdot) \) since it satisfies \( a(t) \in \mathcal{A}(t), \forall t \). However, the set \( \mathcal{B}(\cdot) \)

Email addresses: simon.rohou@ensta-bretagne.fr (Simon Rohou), luc.jaulin@gmail.com (Luc Jaulin)
of all trajectories \( b(\cdot) \), such that \( b(t) \in [-1, 1] \) and \( \dot{b}(t) \geq 0 \), is not a tube.

Now, let us define the inclusion between two tubes as

\[
X(\cdot) \subset Y(\cdot) \iff \forall t, X(t) \subset Y(t).
\]

The set of tubes equipped with the inclusion is a lattice [22]. As a consequence, if we define a set of trajectories \( \mathcal{B}(\cdot) \), there exists a unique smallest tube that encloses \( \mathcal{B}(\cdot) \). For instance, the smallest tube enclosing all trajectories \( b(\cdot) \) defined in \( t \mapsto [-1, 1] \) such that \( \dot{b}(t) \geq 0 \) is the tube \( A(\cdot) : t \mapsto [-1, 1] \).

These definitions also apply when \( t \) is restricted to be inside an interval \([0, \ell]\), representing a temporal domain.

2.2. The input \( u(\cdot) \) is known

Consider the linear time-invariant dynamical system

\[
\dot{x} = Ax + Bu.
\]

Because the system is linear, an analytical expression for the flow is given by

\[
\Phi^{u(\cdot)}_{t_1, t_2}(x_1) = e^{A(t_2 - t_1)}x + \int_{t_1}^{t_2} e^{A(t - t_1)}Bu(\tau)d\tau.
\]

Assume that for \( t \in [0, \ell] \), the state trajectory \( x(\cdot) \) is known to be inside the prior tube \( \bar{X}(\cdot) \). We want to compute recursively the smallest tube \( X(\cdot) \) for \( x(\cdot) \) consistent with both the prior tube \( \bar{X}(\cdot) \) and the state equation. This sequence can be interpreted as an extension to continuous time systems of the state estimator proposed in [23] or [24].

For a given initial vector \( x_1 \) defined at \( t_1 \), the state at time \( t_2 \) is expressed by

\[
x_2 = \Phi^{u(\cdot)}_{t_1, t_2}(x_1),
\]

where \( \Phi^{u(\cdot)}_{t_1, t_2} \) is the flow of the dynamical system according to its input \( u(\cdot) \). The flow can be extended to sets \([25]\) as follows:

\[
\Phi^{u(\cdot)}_{t_1, t_2}(X_1) = \left\{ x_2 \mid \exists x_1 \in X_1, x_2 = \Phi^{u(\cdot)}_{t_1, t_2}(x_1) \right\}.
\]

The dot notation \( (\cdot) \) is used in this paper for representing the independent variable. Also, note that for ease of reading, the notation \( u(\cdot) \) is used in the above equation instead of \( u(t_1, t_2)(\cdot) \), as there is no dependency with the values of \( u(\cdot) \) outside the interval \([t_1, t_2]\).

The following two corollaries will be used thereafter for the proof of Theorem 3.

**Corollary 1.** Given a set \( X_1 \), three time instants \( t_1, t_2, t_3 \), and an input \( u(\cdot) \), we have the Chasles property:

\[
\Phi^{u(\cdot)}_{t_1, t_3}(X_1) = \Phi^{u(\cdot)}_{t_2, t_3} \circ \Phi^{u(\cdot)}_{t_1, t_2}(X_1).
\]

**Proof.** From Equation (3), we have:

\[
\Phi^{u(\cdot)}_{t_2, t_3} \circ \Phi^{u(\cdot)}_{t_1, t_2}(X_1) = \left\{ x_3 \mid \exists x_2 \in \Phi^{u(\cdot)}_{t_1, t_2}(X_1), x_3 = \Phi^{u(\cdot)}_{t_2, t_3}(x_2) \right\}
\]

\[
= \left\{ x_3 \mid \exists x_1 \in X_1, x_2 = \Phi^{u(\cdot)}_{t_1, t_2}(x_1), x_3 = \Phi^{u(\cdot)}_{t_2, t_3}(x_2) \right\}
\]

\[
= \left\{ x_3 \mid \exists x_1 \in X_1, x_3 = \Phi^{u(\cdot)}_{t_2, t_3} \circ \Phi^{u(\cdot)}_{t_1, t_2}(x_1) \right\}
\]

\[
= \left\{ x_3 \mid \exists x_1 \in X_1, x_3 = \Phi^{u(\cdot)}_{t_1, t_3}(x_1) \right\}
\]

\[
= \Phi^{u(\cdot)}_{t_1, t_3}(X_1).
\]

**Corollary 2.** Given two sets \( X^a_1, X^b_1 \), two time instants \( t_1, t_2 \), and an input \( u(\cdot) \), we have the automorphism property:

\[
\Phi^{u(\cdot)}_{t_1, t_2}(X^a_1 \cap X^b_1) = \Phi^{u(\cdot)}_{t_1, t_2}(X^a_1) \cap \Phi^{u(\cdot)}_{t_1, t_2}(X^b_1).
\]

**Proof.** From Equation (3), we have:

\[
\Phi^{u(\cdot)}_{t_1, t_2}(X^a_1 \cap X^b_1) = \left\{ x_2 \mid \exists x_1 \in X^a_1 \cap X^b_1, x_2 = \Phi^{u(\cdot)}_{t_1, t_2}(x_1) \right\}
\]

\[
= \{ x_2 \mid \exists x_1a \in X^a_1, \exists x_1b \in X^b_1, x_2 = \Phi^{u(\cdot)}_{t_1, t_2}(x_1a) \wedge \exists x_1b \in X^b_1, x_2 = \Phi^{u(\cdot)}_{t_1, t_2}(x_1b) \}
\]

\[
= \left\{ x_2 \mid \exists x_1a \in X^a_1, x_2 = \Phi^{u(\cdot)}_{t_1, t_2}(x_1a) \right\} \cap \left\{ x_2 \mid \exists x_1b \in X^b_1, x_2 = \Phi^{u(\cdot)}_{t_1, t_2}(x_1b) \right\}
\]

\[
= \Phi^{u(\cdot)}_{t_1, t_2}(X^a_1) \cap \Phi^{u(\cdot)}_{t_1, t_2}(X^b_1).
\]
Theorem 3. Given the sampling times of measurements\(^3\)
\[
T = \{0, \delta, 2\delta, \ldots, k\delta\} = \{t_0, t_1, t_2, \ldots, t_k\},
\]
and a prior tube \(\tilde{X}(\cdot)\) containing the actual state trajectory \(x(\cdot)\). The posterior tube \(\hat{X}(\cdot)\) can be defined recursively by
\[
\hat{X}_{t_k} = \Phi_{t_{k-1}, t_k}^{u(\cdot)}(\hat{X}_{t_{k-1}}) \cap \bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau)
\]
\[
\hat{X}_{t_k} = \hat{X}_{t_k} \cap \hat{X}_{t_k}
\]
with \(\hat{X}_{t_0} = \hat{X}(t_0)\) and \(\hat{X}_{t_k} = \hat{X}(t_k)\). Moreover, when \(t\) is not consistent with the sampling times (i.e. for \(t \in [t_k, t_{k+1}) \backslash T = \{t_k, t_{k+1}\}\), then we directly have
\[
\hat{X}_t = \Phi_{t_k, t}^{u(\cdot)}(\hat{X}_{t_k}).
\]
Proof. We have the decomposition:
\[
\hat{X}_{t_k} \equiv \bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau) \cap \bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau).
\]
Now,
\[
\bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau) \equiv \bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau).
\]
\[
\bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau) = \Phi_{t_{k-1}, t_k}^{u(\cdot)}(\hat{X}_{t_{k-1}}).
\]
Combined with Equation (11), we obtain the first part of Equations (10).

Then, for the second part, we have
\[
\hat{X}_{t_k} \equiv \bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau) \cap \bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau).
\]

Now,
\[
\bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau) \equiv \bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau) \\
\bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau) = \Phi_{t_{k-1}, t_k}^{u(\cdot)}(\hat{X}_{t_{k-1}}).
\]
which leads to the second part of Equations (10) if combined with Equation (13).

Moreover,
\[
\hat{X}_{t_k} \equiv \bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau)
\]
which corresponds to the last part of Equations (10).

Finally
\[
\hat{X}_{t_k} \equiv \bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau) \\
\bigcap_{\tau \in [t_{k-1}, t_k]} \Phi_{\tau, t_k}^{u(\cdot)}(\hat{X}_\tau) = \Phi_{t_{k-1}, t_k}^{u(\cdot)}(\hat{X}_{t_{k-1}}).
\]
which concludes the proof.

2.3. The input \(u(\cdot)\) is uncertain

The previous results can be extended to the case where \(u(\cdot)\) is uncertain but known to be inside a tube \(U(\cdot)\). This allows to consider bounded errors on the system input. In this case, the set flow given by Equation (3) becomes:
\[
\Phi_{t_1, t_2}^{u(\cdot)}(\hat{X}_1) = \bigcup_{u(\cdot) \in U(\cdot)} \Phi_{t_1, t_2}^{u(\cdot)}(\hat{X}_1).
\]
Furthermore, from Equation (6), the smallest tube \( \hat{X}(\cdot) \) for \( x(\cdot) \) consistent with the prior tube \( \bar{X}(\cdot) \), the input tube \( U(\cdot) \) and the state equation \( \dot{X} = f(x, u) \) is

\[
\hat{X}_t = \bigcup_{u(\cdot) \in U(\cdot)} \bigcap_{\tau \in [0,t]} \Phi^{U(\cdot)}_{\tau,t}(\bar{X}_\tau).
\] (14)

**Remark 4.** Note that for a collection of sets \( \mathcal{A}_{ij} \), we have

\[
\bigcup_{i} \bigcap_{j} \mathcal{A}_{ij} \subset \bigcap_{j} \bigcup_{i} \mathcal{A}_{ij}.
\]

Indeed,

\[
a \in \bigcup_{i} \bigcap_{j} \mathcal{A}_{ij} \iff \exists i, \forall j, a \in \mathcal{A}_{ij}
\]

\[
\iff \forall j, \exists i, a \in \mathcal{A}_{ij}
\]

\[
\iff a \in \bigcap_{j} \bigcup_{i} \mathcal{A}_{ij}.
\]

As a consequence, we obtain the following inclusion for expressing Equation (14) (but not an equality):

\[
\hat{X}_t = \bigcup_{u(\cdot) \in U(\cdot)} \bigcap_{\tau \in [0,t]} \Phi^{U(\cdot)}_{\tau,t}(\bar{X}_\tau)
\subset \bigcap_{\tau \in [0,t]} \bigcup_{u(\cdot) \in U(\cdot)} \Phi^{U(\cdot)}_{\tau,t}(\bar{X}_\tau)
= \bigcap_{\tau \in [0,t]} \Phi^{U(\cdot)}_{\tau,t}(\bar{X}_\tau).
\] (15)

Define the set

\[
\tilde{X}_t = \bigcup_{u(\cdot) \in U(\cdot)} \bigcap_{\tau \in [0,t]} \Phi^{U(\cdot)}_{\tau,t}(\bar{X}_\tau)
\]

which corresponds to the set of all \( x(t) \) consistent with the past (before \( t \)) and

\[
\tilde{X}_t = \bigcup_{u(\cdot) \in U(\cdot)} \bigcap_{\tau \in [t,t]} \Phi^{U(\cdot)}_{\tau,t}(\bar{X}_\tau)
\] (16)

the set of all \( x(t) \) consistent with the future (after \( t \)). The exact sequence Theorem extends as follows.

**Theorem 5.** Given the sampling times of measurements

\[
\mathcal{T} = \{0, \delta, 2\delta, \ldots, k\delta\} = \{t_0, t_1, t_2, \ldots, t_k\},
\]
a prior tube \( \bar{X}(\cdot) \) containing the state trajectory \( x(\cdot) \), and a tube \( U(\cdot) \) for the input. The posterior tube \( \hat{X}(\cdot) \) can be defined recursively by

\[
\hat{X}_{t_0} = \Phi^{U(\cdot)}_{t_0,t_0}(\tilde{X}_{t_0})
\]

\[
\hat{X}_{t_1} = \Phi^{U(\cdot)}_{t_1,t_1}(\hat{X}_{t_1}) \cap \bigcup_{u(\cdot) \in U(\cdot)} \bigcap_{\tau \in [t_0,t_1]} \Phi^{U(\cdot)}_{\tau,t_1}(\bar{X}_{\tau})
\]

\[
\hat{X}_{t_2} = \Phi^{U(\cdot)}_{t_2,t_2}(\tilde{X}_{t_2}) \cap \bigcup_{u(\cdot) \in U(\cdot)} \bigcap_{\tau \in [t_1,t_2]} \Phi^{U(\cdot)}_{\tau,t_2}(\bar{X}_{\tau})
\]

\[
\hat{X}_{t_k} = \hat{X}_{t_{k-1}} \cap \tilde{X}_{t_k}
\] (17)

with \( \tilde{X}_{t_0} = \tilde{X}(t_0) \) and \( \tilde{X}_{t_k} = \tilde{X}(t_k) \). Moreover, for \( t \in [t_k, t_{k+1}] \setminus \mathcal{T} \), we have:

\[
\hat{X}_t = \Phi^{U(\cdot)}_{t,t}(\hat{X}_{t_k}).
\]

**Proof.** From Equation (15), we have

\[
\tilde{X}_{t_k} = \bigcup_{u(\cdot) \in U(\cdot)} \bigcap_{\tau \in [0,t_k]} \Phi^{U(\cdot)}_{\tau,t_k}(\bar{X}_{\tau})
= \bigcup_{u(\cdot) \in U(\cdot)} \bigcap_{\tau \in [0,t_{k-1}]} \Phi^{U(\cdot)}_{\tau,t_k}(\bar{X}_{\tau})
\cap \bigcap_{\tau \in [t_{k-1}, t_k]} \Phi^{U(\cdot)}_{\tau,t_k}(\bar{X}_{\tau})
= \left( \bigcup_{u(\cdot) \in U(\cdot)} \bigcap_{\tau \in [0,t_{k-1}]} \Phi^{U(\cdot)}_{\tau,t_k}(\bar{X}_{\tau}) \right)
\cap \left( \bigcup_{u(\cdot) \in U(\cdot)} \bigcap_{\tau \in [t_{k-1}, t_k]} \Phi^{U(\cdot)}_{\tau,t_k}(\bar{X}_{\tau}) \right).
\] (18)

The distribution of the union operator is allowed here since different instants are involved. Indeed, recall that for two sets \( A \) and \( B \), we cannot state that

\[
\bigcup_{u \in U} (A(u) \cap B(u)) = \bigcup_{u \in U} A(u) \cup \bigcup_{u \in U} B(u).
\]

However, this is allowed when we have independence between the components. For instance, if \( U \) is a box of \( \mathbb{R}^n \), the above expression is allowed when \( A \) depends on some components of \( U \) and \( B \) of some other components of \( U \).

Now,

\[
\bigcup_{u(\cdot) \in U(\cdot)} \bigcap_{\tau \in [0,t_{k-1}]} \Phi^{U(\cdot)}_{\tau,t_k}(\bar{X}_{\tau}) \equiv \bigcup_{u(\cdot) \in U(\cdot)} \Phi^{U(\cdot)}_{t_{k-1},t_k}(\tilde{X}_{t_{k-1}})
= \bigcap_{\tau \in [t_{k-1}, t_k]} \Phi^{U(\cdot)}_{\tau,t_k}(\bar{X}_{\tau}).
\]

Combined with Equation (18), we obtain the first part of Equations (17). A similar reasoning applies to get the sequence for \( \tilde{X}_{t_k} \) and the expression for \( \hat{X}_t \).

\[
\square
\]

3. State estimator

The exact sequence suggested by Theorem 3 is valid even if the system is non-linear. Nevertheless, it can be implemented exactly on a computer only in the linear case.

This is due to the fact that we do have an expression for the flow. This section shows how an accurate approximation of the exact sequence can be implemented.

3.1. Principle

To use Equation (2) in the case where interval uncertainties exist for time \( t \), we need to introduce the concept of exponential for an interval matrix \([A]\) which has to be understood with a set-theoretical meaning [26]. It is defined as the smallest interval matrix which encloses all feasible exponentials of \( A \), assuming that \( A \in [A], \ i.e., \)

\[
e^{[A]} = \left\{ [B] \mid \exists A \in [A], B = e^{A} \right\}.
\]

Moreover, given an interval matrix \([A]\) and a set of vectors \( X \), we define the product \([A] \cdot X \) as the smallest box
enclosing all feasible products $A \cdot x$ assuming that $x \in \mathbb{X}$ and $A \in [A]$, i.e.,

$$[A] \cdot \mathbb{X} = \{ y \mid \exists A \in [A], \exists x \in \mathbb{X}, y = A \cdot x \}.$$  

The following theorem corresponds to an implementation of the exact sequence provided by Theorem 3.

**Theorem 6.** Given the sampling times of measurements

$$\mathbb{T} = \{ 0, \delta, 2\delta, \ldots, k\delta \} = \{ t_0, t_1, t_2, \ldots, t_k \},$$

a prior tube $\mathbb{X}(\cdot)$ containing the state trajectory $x(\cdot)$, and a piecewise constant tube

$$U(\cdot) = \{ u(\cdot) \mid \forall k, \forall t \in [k\delta, (k+1)\delta], u(t) \in [u]_k \}$$

containing $u(\cdot)$, where $[u]_k, k \in \{ 0, \ldots, k-1 \}$ is a slice of the tube $U(\cdot)$ as illustrated by Figure 2. We have

$$\mathbb{X}_{t_k} \subset \mathbb{X}_{t_k} \cap \left\{ e^{A\delta}, \mathbb{X}_{t_k+1} + \delta e^{A[0,\delta]}B[u]_{k-1} \right\}$$

$$\mathbb{X}_{t_k} \subset \mathbb{X}_{t_k+1} \cap \left\{ e^{-A\delta}, \mathbb{X}_{t_k} - \delta e^{-A[0,\delta]}B[u]_k \right\}$$

with $\mathbb{X}_{t_0} = \mathbb{X}_{t_0}$ and $\mathbb{X}_{t_k} = \mathbb{X}_{t_k}$. Moreover for $t \in [t_k, t_{k+1}) \setminus \mathbb{T}$, we have

$$\mathbb{X}_t = \left\{ e^{A(t-t_k)} \cdot \mathbb{X}_{t_k} + (t-t_k) e^A [0,t-t_k]B[u]_k \right\}.$$  

**Proof.** We first show the inclusion for $\mathbb{X}_{t_k}$. We have

$$\mathbb{X}_{t_k} \overset{(17)}{=} \Phi^{U(\cdot)}_{t_k, t_k+1}(\mathbb{X}_{t_{k+1}}) \cap \bigcup_{\tau \in [t_k, t_{k+1}]} \Phi^{U(\cdot)}_{\tau, t_k}(\mathbb{X}_\tau)$$

(Remark 4)

$$\subset \Phi^{U(\cdot)}_{t_k, t_k+1}(\mathbb{X}_{t_{k+1}}) \cap \bigcup_{\tau \in [t_k, t_{k+1}]} \Phi^{U(\cdot)}_{\tau, t_k}(\mathbb{X}_\tau)$$

$$\subset \Phi^{U(\cdot)}_{t_k, t_k+1}(\mathbb{X}_{t_{k+1}}) \cap \Phi^{U(\cdot)}_{t_{k+1}, t_k}(\mathbb{X}_{t_k})$$

$$= \mathbb{X}_{t_k+1} \cap \Phi^{U(\cdot)}_{t_{k+1}, t_k}(\mathbb{X}_{t_{k+1}})$$

$$= \mathbb{X}_{t_k} \cap \left\{ e^{A\delta}, \mathbb{X}_{t_{k+1}} + \int_{t_{k+1}}^{t_k} e^{A(t_{k+1}-\tau)}B(\tau)d\tau \right\}.$$  

Now, because $U(\cdot)$ is piecewise constant,

$$\int_{t_{k+1}}^{t_k} e^{A(t_{k+1}-\tau)}B(\tau)d\tau = \int_{t_{k+1}}^{t_k} e^{A(t_{k+1}-\tau)}B[u]_{k-1}d\tau$$

$$= \int_{t_{k+1}}^{t_k} e^{A[0,\delta]}B[u]_{k-1}d\tau$$

$$= \int_{t_{k+1}}^{t_k} e^{A[0,\delta]}B[u]_{k-1}d\tau$$

$$= \delta e^{A[0,\delta]}B[u]_{k-1}. \quad (20)$$

Therefore,

$$\mathbb{X}_{t_k} \subset \mathbb{X}_{t_k} \cap \left\{ e^{A\delta}, \mathbb{X}_{t_{k+1}} + \delta e^{A[0,\delta]}B[u]_{k-1} \right\}$$

which corresponds to the first part of Equations (19).

We now show the inclusion for $\mathbb{X}_t$. We have

$$\mathbb{X}_t \overset{(17)}{=} \Phi^{U(\cdot)}_{t_{k+1}, t_k}(\mathbb{X}_{t_{k+1}}) \cap \bigcup_{\tau \in [t_k, t_{k+1}]} \Phi^{U(\cdot)}_{\tau, t_{k+1}}(\mathbb{X}_\tau)$$

(Remark 4)

$$\subset \Phi^{U(\cdot)}_{t_{k+1}, t_k}(\mathbb{X}_{t_{k+1}}) \cap \bigcup_{\tau \in [t_k, t_{k+1}]} \Phi^{U(\cdot)}_{\tau, t_{k+1}}(\mathbb{X}_\tau)$$

$$\subset \Phi^{U(\cdot)}_{t_{k+1}, t_k}(\mathbb{X}_{t_{k+1}}) \cap \Phi^{U(\cdot)}_{t_k, t_{k+1}}(\mathbb{X}_{t_k})$$

$$= \mathbb{X}_{t_{k+1}} \cap \Phi^{U(\cdot)}_{t_k, t_{k+1}}(\mathbb{X}_{t_{k+1}})$$

$$= \mathbb{X}_t \cap \left\{ e^{-A\delta}, \mathbb{X}_{t_{k+1}} + \int_{t_{k+1}}^{t_k} e^{A(t_{k+1}-\tau)}B(\tau)d\tau \right\}.$$  

Now, using Equation (20), we obtain

$$\int_{t_{k+1}}^{t_k} e^{A(t_{k+1}-\tau)}B(\tau)d\tau \subset -\delta e^{A[0,\delta]}B[u]_{k-1}.$$  

Therefore,

$$\mathbb{X}_{t_k} \subset \mathbb{X}_{t_k} \cap \left\{ e^{A\delta}, \mathbb{X}_{t_{k+1}} + \delta e^{A[0,\delta]}B[u]_{k-1} \right\}.$$  

which corresponds to the second part of Equations (19). The last part is already known from Equations (17).

\[ \square \]

**3.2. Example: the triple integrator**

Before going into the implementation algorithm, we propose the following example for illustrating the method.
Consider the linear system

\[
\dot{x} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} x + \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} u
\]

equivalent to a triple integrator. We have the flow expressed as

\[
\Phi_{t_1,t_2}^{(1)}(x) = e^{A(t_2-t_1)x} + \int_{t_1}^{t_2} e^{A(t_2-\tau)} Bu(\tau) d\tau,
\]

with

\[
e^{At} = \begin{pmatrix} 1 & t & t^2/2 \\ 0 & 1 & t \\ 0 & 0 & 1 \end{pmatrix}.
\]

From Theorem 6, we get the following inclusions:

\[
\tilde{X}_{t_k} \subset \tilde{X}_{t_{k+1}} \cap \left\{ e^{A\delta} \cdot \tilde{X}_{t_k} + \delta \begin{pmatrix} 0, \delta \end{pmatrix}^2 [u]_{k-1} \right\},
\]

\[
\tilde{X}_{t_k} \subset \tilde{X}_{t_{k+1}} \cap \left\{ e^{-A\delta} \cdot \tilde{X}_{t_k} - \delta e^{-A\delta} [u]_k \right\},
\]

\[
\tilde{X}_{t_k} = \tilde{X}_{t_{k+1}} \cap \tilde{X}_{t_k}.
\]

**Remark 8.** Note that since the system is linear and time invariant (i.e., $A$ does not change with time), we were able to provide a closed form expression for the exponential $e^{At}$. This time invariance is needed by our method.

### 3.3. Implementation

Now that we have defined a reliable enclosure from a bounded input $U()$, that can be numerically represented and guaranteed to enclose $u()$, it remains to reliably compute the sets $\tilde{X}$. Consider a polygon $P_k$ which contains $\tilde{X}_{t_k}$. We apply the following polygonal sequence:

- first, forward in time, for $k \in \{1, \ldots, \bar{k}\}$:

  \[ P_k := P_k \cap \left\{ e^{A\delta} \cdot P_{k-1} + \delta e^{A\delta} B[u]_{k-1} \right\}, \]

- then, backward in time, for $k \in \{\bar{k}, \ldots, 0\}$:

  \[ P_k := P_k \cap \left\{ e^{-A\delta} \cdot P_{k+1} - \delta e^{-A\delta} B[u]_k \right\}, \]

- finally, between the sampling times, $k \in \{0, \ldots, \bar{k}-1\}$:

  \[ P_{k,k+1} := \left\{ e^{A[0,\delta]} \cdot P_k + [0,\delta] e^{A[0,\delta]} B[u]_k \right\}. \]

From Theorem 6, we know that for all $t_k \in T$,

\[
\begin{cases} \tilde{X}_{t_k} \subset P_k, \\ \forall t \in [t_k,t_{k+1}], \tilde{X}_{t} \subset P_{k,k+1}. \end{cases}
\]

An illustration of the polygons $P_k$, $P_{k,k+1}$, $P_{k+1}$ implementing a slice of a tube $\tilde{X}(\cdot)$ is given by Figure 3.

The implementation is close to the exact sequence given by Theorem 3. As a consequence, it is not needed in practice to apply several times the polygonal sequence to obtain an accurate enclosure.

**Remark 9.** When the state estimator is numerically implemented, rounding errors occur. Due to the fundamental theorem of interval analysis [27], an interval implementation with outward rounding makes it possible to get a guaranteed approximation of the exact set. However, it will introduce a small pessimism. The accuracy of the approximation can be made as small as desired if we use a multi-precision interval arithmetic library such as MPFI [28].

### 3.4. Measurements at uncertain times

In this paper, an observation made at some time $t$ consistent with the sampling times $T$ is processed as a restriction on the $\tilde{X}(\cdot)$ prior sets. However, in practice, the time of measurement $t$ is not consistent with $T$. This makes the problem much more difficult if the guarantee is required [29, 30]. Interval analysis can help to deal with this type of estimation [31].

Define as $t_k$ the largest $t_k \in T$ such that $t_k \leq t$. If $[y]$ is a bounded measurement, with $x_t \in [y]$, then we have:

\[
x_t \in e^{-A\tau} \cdot [y] - (t-t_k) e^{-A[0,t-t_k]} B[u]_k.
\]

If now, $t$ is uncertain, but known to belong to $[t_k,t_{k+1}]$, then we have $t - t_k \in [0,\delta]$. Therefore

\[
x_t \in e^{-A[0,\delta]} \cdot [y] - [0,\delta] e^{-A[0,\delta]} B[u]_k
\]

where $\delta = t_{k+1} - t_k$.

Finally, if the uncertainty covers several slices, i.e. $t \in [t_{k_0},t_{k_1}]$, we get

\[
x_{t_0} \in e^{-A[0,\delta]} \cdot [y] - [0,\delta] e^{-A[0,\delta]} B \cdot [u]_{k_0,k_1},
\]

where $\delta = t_{k_1} - t_{k_0}$ and $[u]_{k_0,k_1} = \bigcup_{k \in [k_0,k_1]} [u]_k$.

This is similar to the implementation used in [32] for reliably handling time uncertainties.

### 4. Test case

In this section, we provide an application of the proposed implementation for state estimation. Let us consider...
a car moving on a line over \([0, T] = [0, 10]\). The system is described by

\[
\begin{align*}
\dot{x}_1 &= x_2 \\
\dot{x}_2 &= -x_1 - x_2 + u
\end{align*}
\]

where \(x_1\) corresponds to the position of the car, \(x_2\) to the speed. The initial condition \(x(0) = 0\) is considered unknown. We assume that the thrust \(u\) satisfies \(u \in \cos(t) + \sin(\frac{t}{3}) + \frac{t}{10} + [-0.1, 0.1]\). The state estimation is performed with a time step \(\delta\), which defines the slicing of the input tube \(U(\cdot)\) and the state tube \(X(\cdot)\). Measurements of the state vector \((\tilde{y}_1, \tilde{y}_2)\) are provided at times \(t_i \in [0, T]\) as given in Table 1. Note that the \(t_i\)'s are not necessarily consistent with the sampling times \(k\delta\) we use for the computation. The measurement errors are assumed to be 0.01, \(i.e., \forall t_i, x(t_i) \in \tilde{y}(t_i) + [-0.01, 0.01]^2\).

<table>

</tr>
</tbody>
</table>

The polygonal enclosure of the state trajectory is computed forward and backward in time, allowing to enclose the unknown initial condition \(x(0)\). Results are illustrated in Figure 4 for \(\delta = 0.1\) and \(\delta = 0.01\).

**Remark 10.** The envelop that is computed for different values of \(\delta\) converges towards the exact envelop as shown by Theorem 3. We observe in Figures 5–6 that no significant improvement is observed if we decrease the value of \(\delta\), which illustrates a fast convergence with respect to the sampling time of the tube. The computation time is 0.2 second for \(\delta = 0.1\) and 2 seconds for \(\delta = 0.01\). Note also that when we increase the dimension of the state space, our method requires too much computation if we still keep a small sampling time \(\delta\). However, if we accept some pessimism in the approximation, with values for \(\delta\) not too small, or if the number of measurements is large enough, we may still be able to use our approach to get an accurate and guaranteed approximation of the solution set.

5. Conclusion

In this paper, we have proposed a new state estimator to approximate the state of a continuous-time linear system in a set-membership context, with a set of discrete measurements. The method is both

— accurate, since it is a direct extension of the exact polygonal method used for discrete time systems;

— guaranteed, because the propagation of uncertainties over time is made rigorously by using interval analysis.

If we assume that the sampling time \(\delta\) is infinitely small and that the computer computes exactly with real numbers instead of floating point numbers, then our method can be qualified as exact since it does not introduce any pessimism and does not lose any feasible values.

The proposed combination of a polygonal approach with
interval computations is new in this context. We believe that it is the only way to obtain an estimation that is both accurate and guaranteed. In addition, the same approach allows us to handle rigorously time uncertainties outside the sampling times on which the estimation set is implemented.

It must be underlined that our approach cannot be extended directly to non-linear dynamical systems. However, it is often possible to extract linear differential equations from the dynamics. The method developed here can then be used to deal with these equations, within a constraint propagation process. This will be our main objective for forthcoming work.

Supplementary materials including the sources of the application are available on http://simon-rohou.fr/research/linobs/. This work has been implemented in the Codac library [33], that provides tools for computing sets of trajectories.
